

Lecture 6: Gas Chromatography

Instrumentation

Instrumentation

Columns

There are two types of columns:

Capillary

- wall-coated open tubular (WCOT),
- support coated open tubular (SCOT),
- micropacked, fused silica open tubular (FSOT),

Packed column.

Open tubular is also capillary.

Columns determine selectivity and efficiency of the sample.

Instrumentation

Columns

Instrumentation

Columns

Packed columns contain a finely divided, inert, solid support material (commonly based on diatomaceous earth) coated with liquid stationary phase. Most packed columns are 1.5 – 10 m in length and have an internal diameter of 2 – 4 mm.

Greater sample capacity compared to capillary columns

Gas Chromatography

Packed Columns

- Broader peaks, longer retention times and less resolution
- Improve resolution by using small, uniform particle sizes

Open tubular column

Gas Chromatography

Types of Columns

Packed Columns

Older type of column

Both solid and liquid stationary phase

Best column for preparatory GC and for use with thermal conductivity detectors

Sometimes used for very specific applications (low production volume less of an issue)

Gas Chromatography

Packed Columns

For large-scale or preparative purification on an Industrial scale - purification may be in the kilogram or greater range.

500 L chromatography column

Gas Chromatography

Open Tubular Columns

More commonly used in GC

Much better analytical performance (large N values)

Most common is wall coated format (WCOT)

Variety of diameters (0.25 to 0.53 μm most common) allow high resolution vs. easier injection

Stationary phases are mainly bonded of varying amounts of polarity

Good reliability

Disadvantages: harder to make and much less sample capacity

Gas Chromatography

Open Tubular Columns - capillary

Cross section of a Fused Silica Open Tubular Column

➤ Increasing Resolution

- Narrow columns → Increase resolution

- Resolution is proportional to square of N , where N increases directly with column length – lengths usually available from 7 m to 60 m

Instrumentation

Columns

Wall-coated columns consist of a capillary tube whose walls are coated with liquid stationary phase.

In support-coated columns, the inner wall of the capillary is lined with a thin layer of support material such as diatomaceous earth, onto which the stationary phase has been adsorbed.

SCOT columns are generally less efficient than WCOT columns.

Both types of capillary column are more efficient than packed columns.

Instrumentation

Columns

Packed

-  bead column
-  porous layer
-  conventional

open (capillary)

Porous
Layer
Open

WCOT

PLOT

SCOT

-  capillary column
-  liquid stationary phase
-  porous solid support
-  porous solid support coated w/liquid stationary phase

Gas Chromatography

Open Tubular Columns - capillary

- Increasing Resolution
 - Narrow columns → Increase resolution

Decrease tube diameter

→ Increase resolution

Gas Chromatography

Open Tubular Columns - capillary

➤ Increasing Resolution

- Resolution is proportional to square of N , where N increases directly with column length – lengths usually available from 7 m to 60 m

➔ Increase Column Length

➔ Increase resolution

Gas Chromatography

Open Tubular Columns - capillary

- Increasing Resolution

Increase Stationary Phase Thickness

Increase resolution of early eluting compounds

Instrumentation

Column Materials

- Column tubing supports the stationary phase.
- Needs to be:
 - chemically inert (to prevent sample decomposition)
 - thermally stable
 - robust
 - flexible – form a coil to fit into oven

Instrumentation

Column Materials

Early columns were metal (stainless steel, Cu, Al, Ni) but these were too reactive.

Glass is popular – but fragile

Fused silica columns – weak and subject to atmospheric corrosion. Use a protective outer Al or polymer sheath. These columns are used for most applications.

Parameter	Capillary	Packed
Efficiency (plates/m)	2 000 – 4 000	500 - 1 000
Sample size (ng)	10 - 75	10 – 1 000 000
Relative pressure	Low	High
Relative speed	Fast	Slow
Chemical inertness	Best	Poorest
Flexible column	Yes	No

CHEM 5390

Instrumentation

Columns

Column Activity leads to:

- tailing or skewed peaks**
- partial or total disappearance of a solute**
 - reversible peak adsorption
 - non-reversible peak adsorption
 - breakdown

The surface properties of the column – catalytic or sorptive are important to consider to eliminate column activity.

Instrumentation

Columns

Various surface groups attributed to the silica surface have been identified:

**Isolated
Silanol**

**Vicinal
Silanol**

**Geminal
Silanol**

Siloxane

Instrumentation

Columns

Surface hydroxyl groups can act as proton donors in hydrogen bonding interactions

- very strong sorptive sites for molecules with localized high electron density.

Surface siloxane bridge can act as

- proton acceptors functioning as sorptive sites for molecules such as alcohols

Instrumentation

Columns

Metallic contamination

Metal ions present on the surface of soda lime or borosilicate glasses can function as

- Lewis acid sites absorbing molecules that have regions of localized high electron density such olefins, aromatic compounds, alcohols, ketones and amines. (Lewis acids – a species that accepts an electron pair)

Instrumentation

Columns

Columns are deactivated before use. One method deactivates reactive hydroxyl groups by silanizing or silylating the inner surface of the column.

Typical derivatization reactions are:

- Silylation
- Acylation
- Alkylation
- Esterification

Instrumentation

Columns

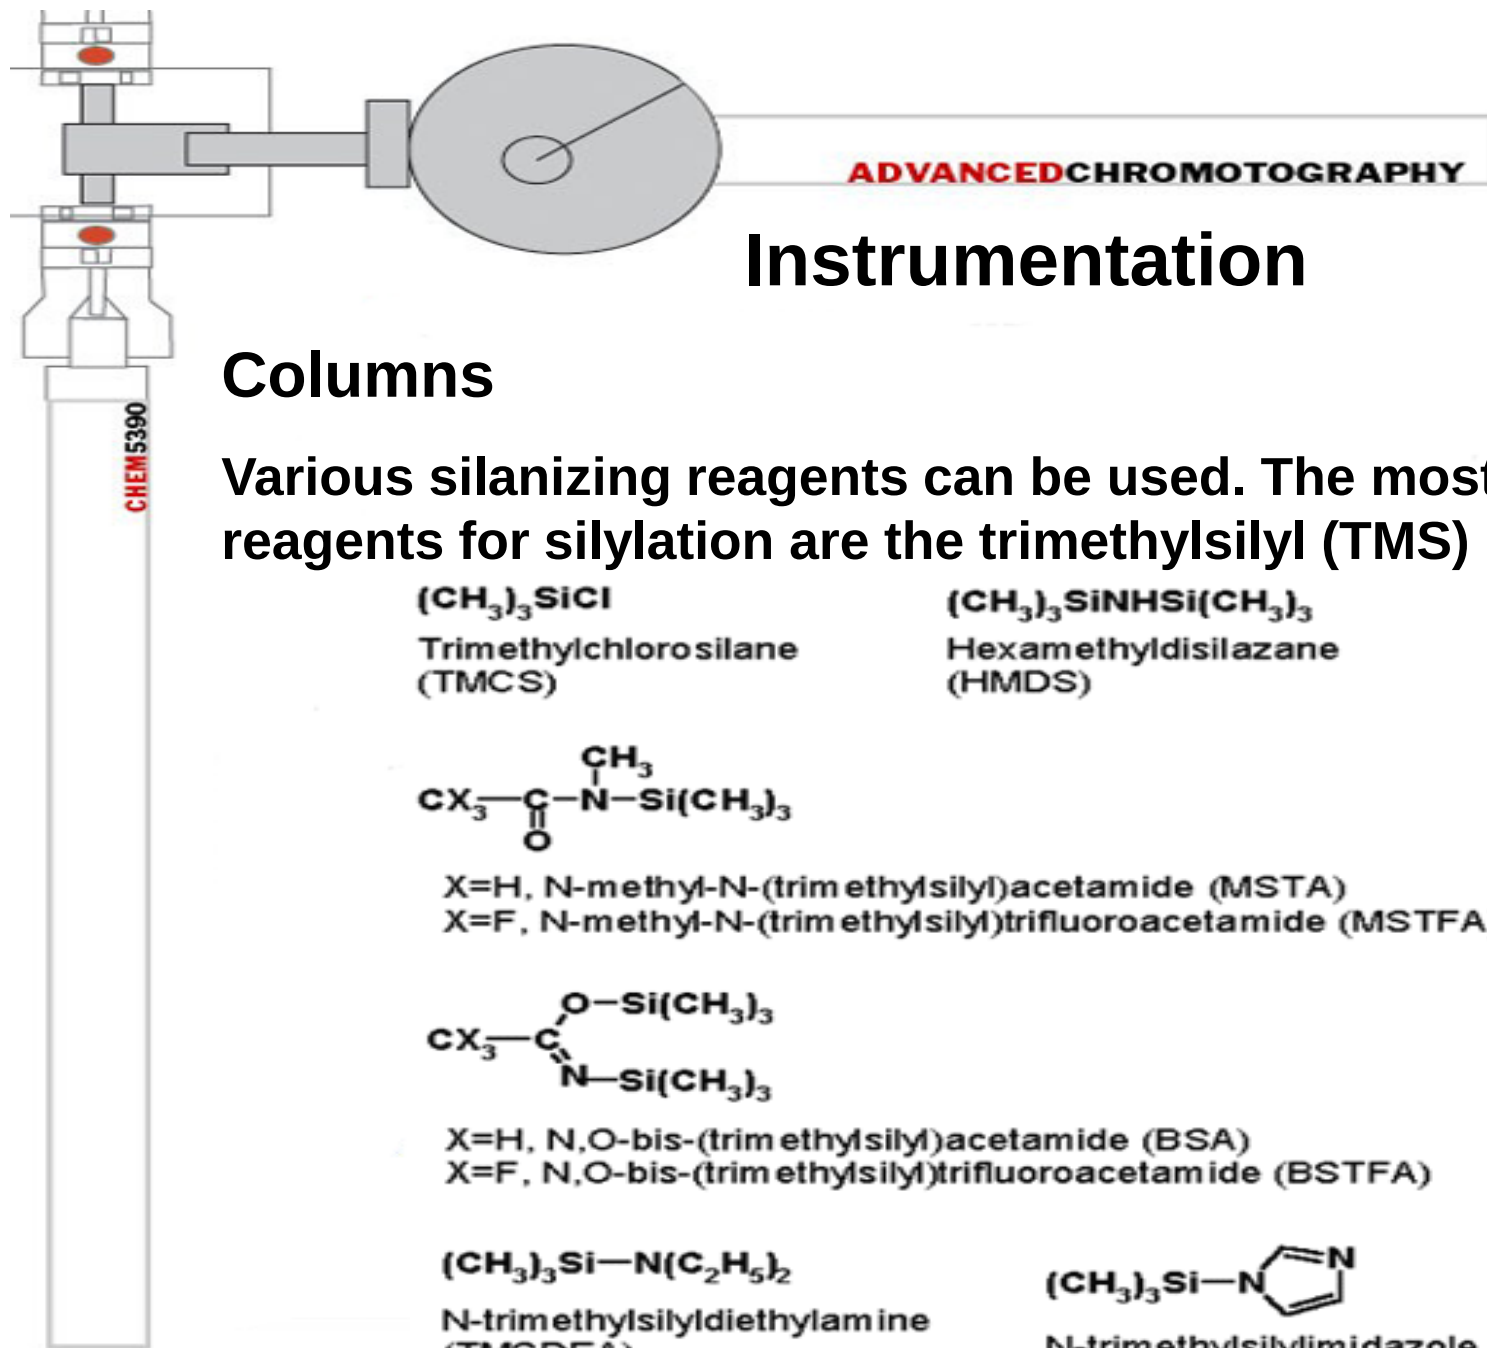

Columns are deactivated before use. Remember that these reactions are used to take care of a “problem” – but can just as well be used to “create” new stationary phases... we will cover this more later.

Instrumentation

Columns

Silylation - It involves the replacement of an acidic hydrogen on the compound with an alkylsilyl group, for example, $-\text{SiMe}_3$. The derivatives are generally less polar, more volatile and more thermally stable.

Instrumentation

Columns

Acylation - Acylation is one of the most widely used derivatization procedures for gas chromatography. Acylation reduces the polarity of compounds that contain active hydrogens (-NH, -OH, -SH amino, hydroxyl and thiol groups) into amides, esters, or thioesters by using carboxylic derivatives.

Columns

The most widely used acylating reagents is acetic anhydride, $(\text{CH}_3\text{CO})_2\text{O}$.

Acylating reagents

Trifluoroacetic anhydride (TFAA)

Pentafluoropropionic anhydride (PFPA)

Heptafluorobutyryl anhydride (HFBA)

Pentafluorobenzoyl chloride

Instrumentation

Columns

Alkylation- Alkylation is the replacement of a active hydrogen in R-COOH, R-OH, R-SH, and R-NH₂ with an alkyl group or, sometimes aryl group.

ADVANCED CHROMATOGRAPHY

Instrumentation

Columns

Alkylating reagents

- Alkyl halide (eg. pentafluorobenzyl bromide, PFBBBr, 3,5-ditrifluoromethylbenzyl bromide)
- Diazoalkane (eg. diazomethane)
- N,N-Dimethylformamide dialkyl acetal
- 3-alkyl-1-p-tolyltriazene
- Fluorosulfonate
- Trimethylanilinium hydroxide (TMAH)
- Trialkyloxonium fluoroborate
- Alkyl trichloroacetimidate

Columns

Functional group

-OH (hydroxyl group) in primary, secondary and tertiary alcohols; phenols; carbohydrates)

-COOH (carboxylic acids)

-C=O (carbonyl group) in aldehydes and ketones

Derivatization

Silylation
 Acylation
 Benzoylation
 Alkylation
 Dansylation
 Reaction with Dis-Cl
 Reaction with FDNB
 Reaction with NBD-Cl
 Ion-pair formation

Esterification
 Silylation
 Ion-pair formation

Oxime formation
 Oxime formation and silylation
 Ketal/acetal formation
 Hydrazone formation
 Schiff's base formation
 Silylation

Functional group

-NH₂ (amino group) in primary amines, amino acids, amino sugars

-NH-R (amino group) in secondary amines, imino acids, substituted amino sugars

-NH₂ and -COOH in amino acids

-NO₂ (nitro compounds)

Gas Chromatography

Conditioning of Columns (stationary phases)

Conditioning for at least 10 h at about 20 °C, above or just close to the upper working temperature of the column

Conditioning must be done below the maximum temperature limit for the stationary phase

Instrumentation

Columns

Stationary Phases

Selection of stationary phase affects k and α values.

Main concerns of stationary phase are:

- polarity,
- functional groups,
- maximum operating temperature, and
- column bleed (loss of stationary phase due to decomposition)

More polar columns suffer from lower maximum temperatures and greater column bleed

Instrumentation

Columns

Stationary Phases (examples)

Type	Functional Groups	Polarity
OV-1	methyl	Non-polar
OV-17	50% methyl/50% phenyl	Somewhat polar
OV-225	Cyanopropyl, methyl, and phenyl	More polar
carbowax	Ether groups	polar

Stationary Phases (examples)

Table 24-1 Common stationary phases in capillary gas chromatography

Structure	Polarity	Temperature range (°C)
$\left[\begin{array}{c} \text{C}_6\text{H}_5 \\ \\ \text{O}-\text{Si} \\ \\ \text{C}_6\text{H}_5 \end{array} \right]_x \left[\begin{array}{c} \text{CH}_3 \\ \\ \text{O}-\text{Si} \\ \\ \text{CH}_3 \end{array} \right]_{1-x}$ (Diphenyl)_x(dimethyl)_{1-x} polysiloxane	$x = 0$ Nonpolar $x = 0.05$ Nonpolar $x = 0.35$ Intermediate polarity $x = 0.65$ Intermediate polarity	$-60^\circ\text{--}320^\circ$ $-60^\circ\text{--}320^\circ$ $0^\circ\text{--}300^\circ$ $50^\circ\text{--}370^\circ$
$\left[\begin{array}{c} \text{CN} \\ \\ \text{O}-\text{Si} \\ \\ \text{C}_6\text{H}_5 \end{array} \right]_{0.14} \left[\begin{array}{c} \text{CH}_3 \\ \\ \text{O}-\text{Si} \\ \\ \text{CH}_3 \end{array} \right]_{0.86}$ (Cyanopropylphenyl)_{0.14}(dimethyl)_{0.86} polysiloxane	Intermediate polarity	$-20^\circ\text{--}280^\circ$
$\text{-(CH}_2\text{CH}_2\text{-O)-}_n$ Carbowax (poly(ethylene glycol))	Strongly polar	$40^\circ\text{--}250^\circ$
$\left[\begin{array}{c} \text{CN} \\ \\ \text{O}-\text{Si} \\ \\ \text{CN} \end{array} \right]_{0.9} \left[\begin{array}{c} \text{CN} \\ \\ \text{O}-\text{Si} \\ \\ \text{C}_6\text{H}_5 \end{array} \right]_{0.1}$ (Biscyanopropyl)_{0.9}(cyanopropylphenyl)_{0.1} polysiloxane	Strongly polar	$0^\circ\text{--}275^\circ$

Stationary Phases (examples)

- Can *manipulate or adjust* retention time by changing polarity of stationary phase

- Can use these retention time differences to classify or rate column performance
 - **Compare relative retention times between compounds and how they change between columns**
- Can be used to identify unknowns

Instrumentation

Columns

Stationary Phases (GSC)

GSC of inorganic gases is the one area where packed columns are still used almost exclusively. Main adsorbents for packed columns are based on:

- silica**
- charcoal**
- alumina**
- molecular sieves**

Instrumentation

Columns

Stationary Phases (GSC)

- Porous silica is used with a variety of surface areas and pore diameters (separate low molecular mass hydrocarbons).
- Alumina has a variety of surface areas – but different selectivities due to Lewis acid sites associated with aluminum ions on the surface. To modify selectivity and improve efficiency, both silica and alumina can be coated with a non-volatile liquid.

Instrumentation

Stationary Phases (GSC)

- Molecular sieves are artificially prepared zeolites (i.e. Na, K, Ca – aluminosilicates) – small pore diameter used to separate low molecular weight molecules and hydrocarbons.

Instrumentation

Stationary Phases (GSC)

- Porous polymers – good for separating polar analytes. Usually consist of copolymers of divinylbenzene (DVB), $\text{CH}_2=\text{CH}-(\text{benzene ring})-\text{CH}=\text{CH}_2$, with another aromatic olefin (ethylene $\text{CH}_2=\text{CH}_2$).

Easy to use and has superior performance and unique separating abilities.

The nature of the separation is adsorption, but the mechanism is unclear.

Scheme 1: Polymerization of DVB

Instrumentation

Columns

Stationary Phases (GSC)

Adsorbents for GSC

<u>Chemical Type</u>	<u>Specific Surface Area (m²g⁻¹)</u>	<u>Pore Diameter (nm)</u>
Silica	~ 100 – 185	15 – 30
Alumina	-	-
Carbon Black	10 – 1000	1 – 2
Molecular Sieves	700 – 1000	0.5 – 2.0
Porous Polymers	~ 100 – 800	5 – 500

Instrumentation

Columns

Stationary Phases (GLC)

Liquid Phase – required properties

- low vapor pressure
- thermal and chemical stability
- high viscosity
- nonreactive toward sample components
- wide operating temperatures (-80 to 450°C)
- reasonable solvent properties

Gas Chromatography

Columns (stationary phases) Examples for GLC

100% dimethyl polysiloxane

Non-polar, Stable to 360°C

Uses: solvents, waxes, petroleum and pharmaceutical samples

5% diphenyl - 95% dimethyl polysiloxane

Non-polar, Stable to 360°C

Uses: flavors, environmental samples, aromatic hydrocarbons

Carbowax® PEG

Polar, Stable to 250°C

Uses: fatty acids, flavors, acids, amines, solvents, xylene

50% cyanopropylphenyl - 50% phenylmethyl polysiloxane

Polar, Stable to 260°C

Uses: fatty acids, carbohydrates

Gas Chromatography

Columns (stationary phases) Examples for GLC

20% diphenyl - 80% dimethyl polysiloxane

Slightly polar, Stable to 310°C

Uses: volatile compounds, alcohols

6% cyanopropylphenyl - 94% dimethyl polysiloxane

Slightly polar, Stable to 280°C

Uses: volatile compounds, insecticides, residue solvents in pharmaceutical products

14% cyanopropylphenyl - 86% dimethyl polysiloxane

Intermediately polar, Stable to 280°C

Uses: pesticides, Aroclors, alcohols, oxygenates

65% diphenyl - 35% dimethyl polysiloxane

Intermediately polar, Stable to 370°C

Uses: triglycerides, rosin acids, free fatty acids

Assignment

- Read Chapter 3: Principles and Practice of Modern Chromatographic Methods, Peter E. Jackson, Academic Press.
- Read Chapter 3: Analytical Gas Chromatography, Walter Jennings, Academic Press. – it is available as an ebook at the UNT Libraries.
